Questions on ADABOOST

Q1. Dataset

Use the **SMS Spam Collection Dataset**
(Source: UCI / Kaggle → spam.csv)

Task

Classify SMS messages as:

- spam (1)
- ham (0) — not spam

Data Description

Column	Meaning
label	spam / ham
text	SMS message content

There are ~5,500 messages

Part A — Data Preprocessing & Exploration

1. Load the SMS spam dataset
2. Convert label: "spam" → 1, "ham" → 0
3. Text preprocessing:
    - Lowercase
    - Remove punctuation
    - Remove stopwords
4. Convert text to numeric feature vectors using **TF-IDF vectorizer**
5. Train–test split (80/20)
6. Show class distribution

Part B — Weak Learner Baseline

Train a **Decision Stump**:

DecisionTreeClassifier(max_depth=1)

Report:

- Train accuracy
- Test accuracy
- Confusion matrix
- Comment on why stump performance is weak on text data

Part C — Manual AdaBoost (T = 15 rounds)

Implement AdaBoost **from scratch** and after **each iteration, print:**

- Iteration number

- Misclassified sample indices
- Weights of misclassified samples
- Alpha value

Then update and normalize weights.

Also produce:

- Plot: iteration vs weighted error
- Plot: iteration vs alpha

Finally report:

- Train accuracy
- Test accuracy
- Confusion matrix
- Short interpretation of weight evolution

Part D — Sklearn AdaBoost

Train:

```
AdaBoostClassifier(
   base_estimator=DecisionTreeClassifier(max_depth=1),
   n_estimators=100,
   learning_rate=0.6
)
```

Report:

- Train accuracy
- Test accuracy
- Confusion matrix
- Compare performance with manual implementation

Q2. Dataset Description

You will use the **UCI Heart Disease dataset** (available in sklearn.datasets). This dataset contains patient medical features used to predict heart disease.

Feature	Meaning
Age	Patient age
Sex	Gender (1 = male, 0 = female)
Cp	Chest pain type (0–3)
Trestbps	Resting blood pressure
Chol	Serum cholesterol (mg/dl)
Fbs	Fasting blood sugar >120 mg/dl (1/0)
Restecg	Resting ECG results
Thalach	Max heart rate achieved
Exang	Exercise-induced angina (1/0)
Oldpeak	ST depression induced by exercise
Slope	Slope of peak exercise ST segment
Ca	# of major vessels (0–3)
Thal	Thallium stress test result (0–3)

Target:
1 = heart disease present
0 = No heart disease

Part A — Baseline Model (Weak Learner)

1. Load the dataset and preprocess (handle categorical features, scaling if needed)
2. Train **one Decision Stump** (max_depth = 1)
3. Report:
    - Training & test accuracy
    - Confusion matrix
    - Classification report
4. What shortcomings do you observe in a single stump?

Part B — Train AdaBoost

1. Train **AdaBoostClassifier** using decision stumps as base learners
2. Use:
    - n_estimators = [5, 10, 25, 50, 100]
    - learning_rate = [0.1, 0.5, 1.0]
3. For each combination:
    - Train model
    - Compute accuracy on test set
4. Plot:
    - n_estimators vs accuracy for each learning_rate
5. Identify best config (highest accuracy)

Part C — Misclassification Pattern

1. For the **best model**, collect the **sample weights** and **prediction errors** at each iteration.
2. Plot:
    - Weak learner error vs iteration
    - Sample weight distribution after final boosting stage
3. Explain:
    - Which samples got highest weights?
    - Why does AdaBoost focus on them?

Part D — Visual Explainability

1. Plot feature importance from AdaBoost.
2. Identify top 5 most important features.
3. Explain why these features may matter medically.

Q2. Dataset:

WISDM Smartphone & Watch Motion Sensor Dataset
(Available on UCI / Kaggle → WISDM_ar_v1.1_raw.txt)

Dataset Description

Collected from smartphones & smartwatches using **accelerometer & gyroscope**.

Attribute	Description
user_id	Person ID
Activity	type of physical activity (e.g., walking, jogging, sitting)

Timestamp	time in milliseconds
sensor readings	acceleration or gyroscope X, Y, Z values

Target prediction task:

- Convert activity into **binary label**:
  - **1** = vigorous motion (Jogging, Upstairs)
  - **0** = light/static motion (Walking, Sitting, Standing, Downstairs)

We will use only **accelerometer features** (X, Y, Z).

Goal

Build an activity classifier using **AdaBoost** to distinguish between **vigorous vs normal activity** based on smartphone sensor accelerations.

Part A — Data Preparation

1. Load the dataset (WISDM_ar_v1.1_raw.txt)
2. Extract only numeric accelerometer X, Y, Z columns
3. Create activity label as binary:

Activity Type	Label
Jogging, Up	1
Walk, Sit, Stand, Down	0

4. Handle missing/dirty entries
5. Train-test split (70/30)

Part B — Weak Classifier Baseline

Train a **Decision Stump**:

DecisionTreeClassifier(max_depth=1)

Report:

- Accuracy (train + test)
- Confusion matrix
- Interpretation of stump result

Part C — Manual AdaBoost (T = 20 rounds)

Write your own AdaBoost **with full weight tracking**.

At **each iteration**, print:

- Iteration number
- Misclassified sample indices
- Weights of misclassified samples

Note: Normalize weights after update.

Also plot:

- Boosting round vs error
- Boosting round vs alpha

Finally report:

- Train accuracy
- Test accuracy
- Confusion matrix
- Interpretation: how weights shifted over time

Part D — Sklearn AdaBoost

Train:

```
AdaBoostClassifier(
   base_estimator = DecisionTreeClassifier(max_depth=1),
   n_estimators = 100,
   learning_rate = 1.0
)
```

Report:

- Train/Test accuracy
- Confusion matrix
- Compare with your manual implementation
